

Q:- In java every object has hash Code
find out what is hash Code why it is
been generated in java

A) A hash code is an integer value generated for every object in java. It is obtained using the `hashCode()` method, which is present in object class.

```
student s = new student();  
System.out.println(s.hashCode());
```

- * The `hashCode()` method returns an integer value for object.
- * Hash codes are mainly used to store and find objects quickly in hash-based collections such as `HashMap`, `HashSet` and `Hashtable`. Java uses the hash code to decide where an object should be stored and where to search for it.
